ANNEX 1. LIST OF SUSTAINABILITY INITIATIVES REVIEWED ............................... 39
ANNEX 2. INDICATORS MATRIX AND GUIDANCE DOCUMENTS .......................... 39
Introduction

The Delta Sustainability Framework aims to align sustainability monitoring and reporting within and across the cotton and coffee sectors. It provides a common set of 15 impact and outcome indicators to measure and report on sustainability improvements as well as guiding principles to gather and communicate sustainability information.

The guiding principles draw inspiration from the ISEAL’s Sustainability Claims Good Practice Guide to communicate relevant sustainability information generated through the common set of indicators, building on the principles of reliability, relevance, clarity, transparency, and accessibility.

The framework has a strong alignment to the Sustainable Development Goals (SDGs) to promote the adoption of a common language and approach to the goal of achieving global sustainable agriculture.

Scope of the framework

The Delta Sustainability Framework is intended to apply worldwide to any cotton and coffee farming system, with the potential to be expanded to other agricultural commodities over time. The scope is the farm, with the single exception of the indicator on greenhouse gas emission estimation which includes cotton ginning. Results however can, and often would need, to be aggregated at higher levels to be more informative.

Most of the environmental and social impacts of agriculture are felt at a larger scale than the farm. As landscape monitoring systems using remote sensing become more accessible, the Delta Project team aims to upgrade the framework indicators and methodologies to a landscape approach (e.g. living income, deforestation risk maps, social risk maps).

The Delta Project team also fully recognises the relevance of expanding the scope of the framework to cover other segments of the value chain in future.

---

1 SEEP is an expert panel of the International Cotton Advisory Committee (ICAC) established in 2006: https://www.icac.org/CommitteesandNetworks/CommitteesandNetworks?CommitteeTypeId=4&MenuId=61
Intended uses

The intended uses of the Delta Sustainability Framework include:

- National reporting on the commitments set by the SDGs and the ratification of relevant international conventions on chemicals, climate change, biodiversity and labour rights;
- Evidence-based recommendations to streamline sustainability in agricultural policies;
- Upgrading of extension services to support continuous improvement at farm level;
- Transparency and communication with consumers on the actual value of sustainably produced goods;
- Identification of business opportunities leveraging sustainable value chains.

Consultations with the sector stakeholders

The common set of indicators is the result of an intensive consultation process that began in June 2019 and engaged sustainability standards, retailers, donors, research institutes, national committees and international organisations from the agricultural sector. In addition to the project partners, the members of the Cotton 2040 platform, the SEEP members representing the Government of 10 countries and the European Union, the Australian Sustainability Working Group, the ISEAL Secretariat and some ISEAL members such as Bonsucro and Rainforest Alliance, have provided substantial input to the development of the indicator set through workshops, webinars, on-line surveys and one-to-one calls. Technical expert group such the Global Soil Partnership have been consulted on methodological guidance on specific indicators.

Sustainability areas and goals

Key sustainability priority areas and sub-areas for coffee and cotton production were identified at the start of the project and validated in the initial consultations held with the stakeholders. The sustainability issues covered directly link to several SDGs targets and in particular to those under SDGs 1, 2, 3, 5, 6, 8, 10, 12, 13, 14 and 15.

</tr>
<tr>
<td></td>
<td>Sustainable cotton farming protects and regenerates ecosystem services</td>
<td>Sustainable cotton farming is economically viable and farmers are economically resilient</td>
</tr>
<tr>
<td></td>
<td>Sustainable cotton farming reduces greenhouse gas emissions and builds resilience to climate change</td>
<td>Sustainable cotton farming alleviates poverty</td>
</tr>
</tbody>
</table>

These goals have yet to be validated with the coffee stakeholders.
The Delta sustainability indicator set

Over 200 indicators currently in use by cotton and coffee specific initiatives as well as more generic sustainability frameworks were assessed during the consultation process for their fitness to monitor progress towards the nine goals. The list of initiatives reviewed is provided in Annex 1.

As a result, the Delta Sustainability Framework comprises a core set of 15 farm-level, outcome/impact indicators across the social, economic and environmental dimensions of sustainability. Considering the interdependences between the social, economic and environmental sustainability pillars, the set of common indicators needs to be seen as a whole.

The indicators were selected for their relevance, usefulness and feasibility in monitoring progress towards sustainable agricultural commodities.

- **Relevance**: progress towards goals and credibility
- **Usefulness**: global commitments, comparability and aggregation, stakeholders' needs
- **Feasibility**: easy of data collection and costs.

1. Use of Highly Hazardous Pesticides
2. Pesticide risk indicator
3. Water management (in irrigated farms)
   3.1 Quantity of water used for irrigation
   3.2 Water use efficiency
   3.3 Water Crop Productivity
4. Top Soil carbon content
5. Fertilizer use by type *(in future: Nitrogen use efficiency)*
6. Forest, wetland and grassland converted for cotton or coffee production
7. Greenhouse Gas Emissions
8. Average yield
9. Net average returns from cotton and coffee production *(in future: Living Income)*
10. Price at farmgate
11. Proportion of workers earning a legal minimum wage
12. Incidence of the worst forms of Child Labour
13. Incidence of Forced Labour
14. Women empowerment
15. Number of fatalities and non-fatalities on the farm

Some indicators include the monitoring of practices to better interpret changes at the outcome level, e.g. good soil management practices to explain changes in organic soil content. In general, the SDG 4.2.1 guidance indicates that measuring sustainability performances through farm practices presents several challenges. The impact of a given practice often varies from one place to another, and from one farm type to another, and what can be considered sustainable in one setting may not be suitable in another.
General definitions

- **FARM**: All types of agricultural holdings to be taken into consideration, with the exception of hobby farms.\(^3\)
- **FAMILY AND SMALL-SCALE FARMING** is a means of organizing agricultural production which is managed and operated by a family and predominantly reliant on family labour. (adapted from Fairtrade)
- **SMALL-SCALE PRODUCERS** are farmers who are not structurally dependent on permanent hired labour and who manage their production activity mainly with family workforce.

---

\(^3\) The characteristics of “hobby farms” are highly context-specific. For instance, in some countries the lower bound for considering an activity as “professional” is a revenue of 1000 USD per year. In other poorer countries, the application of such lower bound would actually exclude from the set of small-scale food producers poor farmers, fisherman and forester who would deserve much attention under SDG 2.3. The only possible solution to this problem seems to be a country-specific lower bound.

Description of the indicators

1. USE OF HIGHLY HAZARDOUS PESTICIDES

Phasing out the use of highly hazardous pesticides is a shared goal of sustainability initiatives. This indicator measures the use of Highly Hazardous Pesticides (HHPs, such as aldicarb, benomyl, carbofuran, dicofol, endosulfan, etoprophos, lindane, methamidophos, monocrotophos, paraquat parathion-methyl, phorate, etc.) in cotton and coffee production. Highly hazardous pesticides are of particular concern due to the severe adverse effects they can cause to human health and the environment, especially in developing countries where protective personal equipment is mostly unavailable, costly and uncomfortable, where pesticides and application equipment are stored in homes, and where accidental or intentional exposure to pesticides is common.

**Definitions**

**Highly hazardous pesticides:**
Highly hazardous pesticides are pesticides that are acknowledged to present particularly high levels of acute or chronic hazards to health or environment according to internationally accepted classification systems such as the World Health Organization (WHO) or the Globally Harmonised System of Classification and Labelling of Chemicals (GHS) or their listing in relevant binding international agreements or conventions. In addition, pesticides that appear to cause severe or irreversible harm to health or the environment under conditions of use in a country may be considered to be and treated as highly hazardous (FAO/WHO International Code of Conduct on Pesticide Management, 2014).

The definition explicitly includes WHO Class 1a and 1b pesticides, GHS Class 1A and 1B carcinogens, mutagens and reproductive toxicity listed pesticides, pesticides listed under Annex III of the...
Rotterdam, Annex A and B of the Stockholm Conventions and Annexes of the Montreal Protocol and pesticide active ingredients and formulations that have shown a high incidence of severe or irreversible adverse effects on human health or the environment.

Joint Meeting on Pesticide Management (JMPM)\(^4\) FAO/WHO criteria for highly hazardous pesticides:

1. Pesticide formulations that meet the criteria of classes la or lb of the WHO Recommended Classification of Pesticides by Hazard; or
2. Pesticide active ingredients and their formulations that meet the criteria of carcinogenicity Categories 1A and 1B of the Globally Harmonized System on Classification and Labelling of Chemicals (GHS); or
3. Pesticide active ingredients and their formulations that meet the criteria of mutagenicity Categories 1A and 1B of the Globally Harmonized System on Classification and Labelling of Chemicals (GHS); or
4. Pesticide active ingredients and their formulations that meet the criteria of reproductive toxicity Categories 1A and 1B of the Globally Harmonized System on Classification and Labelling of Chemicals (GHS); or
5. Pesticide active ingredients listed by the Stockholm Convention in its Annexes A and B, and those meeting all the criteria in paragraph 1 of annex D of the Convention; or
6. Pesticide active ingredients and formulations listed by the Rotterdam Convention in its Annex III; or
7. Pesticides listed under the Montreal Protocol; or
8. Pesticide active ingredients and formulations that have shown a high incidence of severe or irreversible adverse effects on human health or the environment.

**Methodological notes**

**Provisional text pending final endorsement by the Pesticide Working Group**

List of Highly Hazardous Pesticides (HHPs). A list of HHPs reported to be used on cotton and coffee production is provided in Annex X. It should be noted that:

- Annex X is a reference, not an exhaustive list of all the highly hazardous pesticides used in coffee and cotton production globally. It has been compiled based on the information available with the Delta Project Team at the time of the development of this framework;
- Annex X requires regular updates against revisions of hazard classifications and new chemical conventions’ decisions (criteria 1 to 7);
- The monitoring of this indicator will require local contextualization primarily to identify if any additional pesticides, not included in the Annex, have shown a high incidence of severe or irreversible adverse effects on human health or the environment under specific conditions of use (criterion 8);

- Plans for phasing out HHPs should consider availability of alternatives, and if these are not available, the need for research (level of investment, time) to provide alternatives.

- Plans for phasing out HHPs should also consider and address potential unintended consequences as a result of their phasing out, for example the potential for over-use of alternatives and associated impacts, e.g. development of resistance.

**Reporting.** During the phase out period, results can be reported in reduction of kgs of each listed active ingredient used per ha of harvested land. As the 0 target is being reached, results can also be reported by area with no use of HHPs and/or number and percent of smallholder farmers reporting phasing out of listed HHPs.

**REFERENCES**

2. **PESTICIDE RISK INDICATOR**

Pesticide risk models or indicators are tools, based on modelling or actual data from monitoring studies or surveys, which predict the potential risk from the use of pesticides to human health and the environment. These indicators are more informative than the actual pesticide use data *per se* and they are intended to help sustainability initiatives and governements tracking progress in pesticide risk reduction.

There are several complex models and indicators available to evaluate the environmental fate of plant protection products as well as occupational health and bystanders exposure risk to pesticides. OECD has published a comprehensive guidance document to assist policy makers in the selection of the appropriate indicators based on the protection goals that have been set. The models currently used in the European context for pesticide registration have gained international reputation and can be all used in the context of this framework.

There are however two simplified indicators, out of the several options, that are already in use within the cotton sector, namely the Environmental Toxic Load (ETL) and the Toxic Load Indicator (TLI). Both these indicators have a low data requirement (actual total pesticide use by active ingredient) and can provide estimates of the potential pesticide risk useful to improve pesticide management at farm level. As information on actual exposure are not accounted for, both indicators do not measure the actual risk (i.e., the probability of an adverse effect on organisms).

The Environmental Toxic Load (ETL) indicator represents the average amount of toxic pressure caused by the application of pesticides on one (1) hectare of cotton in one (1) year. The ETL can only be used to evaluate the impact of changes in pesticide use on environmental hazards between years and countries. The indicator is based on the quantitative information on pesticide use and the environmental toxicity of the considered pesticides. ETL environmental categories include risk to algae, waterfleas (*Daphnia* species), fish, birds and honey bees.

The Toxic Load Indicator (TLI) is a qualitative indicator for pesticide active ingredients which translates numerical and non-numerical values (toxicological endpoints, classifications) into a scoring system to measure and compare pesticide use (current use and trends). TLI environmental categories include risk to algae, waterfleas (*Daphnia* species), arthropods, fish and birds. It also includes an acute and chronic health risk category.

**REFERENCES**

3. **WATER MANAGEMENT (IN IRRIGATED FARMS)**

This suite of indicators provides an indication of how effectively irrigation water is used on the farm. It includes the total irrigation water used, the efficiency in supplying the water used (water withdrawn or diverted from its sources versus water used) and the amount of marketable biomass produced in relation to the irrigation water used. Sustainable agriculture requires that the level of use of freshwater for irrigation does not affect water reserves. While these indicators do not directly address the issue of water depletion, increasing water use efficiency is a key aspect of ensuring sustainable withdrawals and supply of freshwater. Irrigation systems in cotton and coffee differ from drip irrigation to surface irrigation methods. In most of the cases, there are opportunities to improve efficiency by reducing water losses.

Notwithstanding the relevance of these water metrics to all irrigated farms, concerns remain on their feasibility in small-scale farming for both cotton and coffee where water use and soil moisture records are mostly not available. Additional consultations will be held during the project’s pilots to verify the feasibility and costs associated with the application of these indicators and alternative, simplified options.

### 3.1 QUANTITY OF WATER USED FOR IRRIGATION

### 3.2 WATER USE EFFICIENCY

### 3.3 WATER CROP PRODUCTIVITY (WCP)

</tr>
</tbody>
</table>

**DEFINITIONS AND CALCULATION FORMULA**

**3.1 Water used for irrigation:**

Water used for irrigation provides a measure of the total amount of water used to grow the crop in the field. This indicator however does not take into account the use efficiency: either in terms of the...
actual production of marketable produce associated with that water use, or in terms of water losses between the point of extraction and delivery to the crop.

3.2 Water Use Efficiency (WUE) (%)

Water use efficiency (%) is the ratio between the amount of water actually used for the crop and the amount of water withdrawn or diverted from its source (rivers, lakes, bores etc). It is sometimes also referred to as “water supply efficiency” or “irrigation efficiency” (FAO, 2008). Water use efficiency is therefore a measure of water losses occurring from the storage points to and onto the field.

Crop water use is calculated as the actual evapotranspiration (ET) from the field (FAO, 2012). Evapotranspiration is a combination of two separate processes whereby water is lost from the soil surface through evaporation and used by the crop through transpiration.

Formula: \[
\text{Crop water use (ET)} - \text{Rainfall} - \text{Soil moisture change} \times 100 \div \text{Water used for irrigation}
\]

3.3 WATER CROP PRODUCTIVITY (WCP)

Water Crop Productivity the quantity of output (Kg cotton lint or GBE / Ha) in relation to the volume of water used to produce this output (FAO, 2008). This indicator is a measure of the marketable biomass produced in relation to the water used. Water consumption accounts for irrigation, rainfall and water stored in the soil and it is measured as the actual evapotranspiration.

Formula: \[
\text{Cotton yield}^5 (\text{tonnes cotton lint/ha harvested land}) \text{ OR GBE} \div \text{Water used for irrigation + rainfall + soil moisture change}
\]

This formula does not account for the biomass produced in marketable by-products, as a result the water crop productivity overestimates the amount of water used to produce the commodity. For cotton, a separate WCP measure for cotton seed could be included. Notwithstanding that the above two formula are the most accurate, the measurement of soil moisture changes in countries with limited field research capacity has been raised as a concern and deserves further feasibility investigations.

METHODODOLOGICAL NOTES

Soil moisture. Soil moisture can be measured with a specific appliance such as tensiometer. In the absence of any specific equipment, the Gravimetric Weight Method provides a good alternative to determine soil moisture content by weighing soil samples, drying them in an oven, weighing them again, and using the difference in weight to calculate the amount of water in the soil. This method is

---

5 Yield calculated as indicated under Indicator 8
laborious and time consuming, but low-cost and rather accurate. Guidance on the use of this technique can be found in the Soil testing methods manual (see references).

If accurate soil moisture measures are not available or challenging to obtain, a modified version of WUE and WCP without the soil moisture component can be used. These are referred as partial WUE and WCP, as they are computed without the soil moisture data. Soil moisture is usually a minor component as compared to the other factors in the formula and therefore its exclusion is not expected to affect dramatically the overall trends in data. It is important, however, to specify when the partial formula has been used for comparability purposes.

**Mixed systems.** Cotton and coffee are often grown in spatial combination with other crops. In mixed farming systems (e.g. intercropped fields), crop water use and water crop productivity for cotton and coffee can be calculated based on the estimated land area under each crop grown in the field.

**Rainfed cotton.** Inclusion of indicators on water availability and water scarcity in combination with geo-referenced risk maps is being explored for the next version of the Delta Sustainability Framework.

4. **Top soil carbon content**

This indicator measures the Soil Organic Carbon (SOC), which is the main component of Soil Organic Matter (SOM), in the top layer of the soil (0-10/30 cm) over time. Soil organic matter is increasingly being recognised for its contribution to nutrient cycling, water retention, biological function and optimising crop growth. The last Intergovernmental Panel on Climate Change (IPCC) report on climate change and land considers SOC management as one of the most cost-effective options for climate change adaptation and mitigation. Countries signatories of the United Nations Framework Convention on Climate Change (UNFCCC) are committed to monitor and report SOC stock changes. Sustainable agricultural systems therefore integrate practices aimed at conserving soil resources and enhancing soil carbon content. On the contrary, large-scale monocultures, if not properly managed, can negatively impact soil health as a result of reduced soil biodiversity and increased erosion.

| SDG reference | 15.3.1 Proportion of land that is degraded over total land area |

**Definition**

**Soil organic matter (SOC).** Soil organic matter refers to all decomposed, partly decomposed and undecomposed organic materials of plant and animal origin (FAO, 2017).

**Methodological notes**

Determination of organic soil concentration with the current methods in use remain complex and expensive. Therefore, the indicator combines yearly visual assessments of soil color and biological activity for monitoring purposes, with actual topsoil testing every 5 years that can be reported. It is also recommended to monitor soil management practices to reduce soil erosion and soil fertility losses.
**Visual assessment:** The simplest method for visual assessment and colour determination is the Munsell Notation System. The soil testing methods manual provides guidance on assessing soil color with farmers (see references). A more accurate but expensive method is the portable spectrophotometer (CieLab color) which avoids the human error associated with the interpretation and/or perception of the colour of the sample.

**Laboratory testing protocols:** The Global Soil Laboratory Network (GLOSOLAN) has been recently established to harmonize existing soil laboratory procedures, standards for results’ interpretation and provision of recommendations to farmers. The Delta Sustainability Framework will align with the Standard Operating Procedures (SOPs) proposed by GLOSOLAN to harmonize organic and total carbon measure. SOPs offer step-by-step instructions on how to perform laboratory analyses. For SOC the Walkley-Black method (Titration and colorimetric method) and the Dumas dry combustion method are recommended.

A step-wise approach is proposed to carry out visual assessment and establish a baseline in the first year of testing.

Step 1 – Use the same soil sample for laboratory testing and visual assessment;

Step 2 - Read and record the soil sample colour using a Munsell chart using the guidance provided on the Munsell official site:  [https://munsell.com/about-munsell-color/how-color-notation-works/how-to-read-color-chart/](https://munsell.com/about-munsell-color/how-color-notation-works/how-to-read-color-chart/);

Step 3 - Estimate the organic matter content based on the Munsell soil colour value using the values reported in the table below;

<table>

</tr>
</tbody>
</table>

Note: If chroma is 3.5-6, add 0.5 to value; if chroma is 6, add 1.0 to value.

Source: Adapted from Schlichting, Blume and Stehr, 1995.
Step 4 - Compare results from step 3 with the results from the laboratory to re-calibrate the visual assessment and establish the baseline.
Good soil management practices include:

- Increase biomass production by increasing water availability for plants with soil water conservation and adequate irrigation management;
- Balanced fertilizer applications with appropriate and judicious fertilizer application methods, types, rates and timing;
- Effective use of organic amendments, such as animal manure, compost, digestates, biochar;
- Managing crop residues: using forage by grazing rather than harvesting, applying mulches or providing the soil to give permanent cover;
- Use of cover crops and/or perennials in crop rotations;
- Reducing tillage events and intensity and/or adopting new residue management techniques, minimum or no-tillage;
- Implementing crop rotations with more crops;
- Landform management modification such as those implemented for erosion control (e.g. terraces), surface water management, and drainage/flood control.

5. **Fertilizer use by type (Nitrogen Use Efficiency in future)**

This indicator provides data on inorganic fertilizers, in terms of nutrient content, for the three crop nutrients: Nitrogen (N), Phosphorus (P) and Potassium (K). An accounting of synthetic fertilizer types and quantities represents a proxy for understanding soil management practices and quality. Although it does not *per se* capture the efficiency of the application, it is relevant to pollution prevention strategies. In future, this indicator might also include organic fertilizers, in alignment with the Coffee Global Standard.

**Data collection** Yearly

**Reporting** Yearly

**Data sources** NPK fertilizer applications/purchases

**SDG reference** 2.4.2. - management of fertilizer

**Methodological notes**

**Fertilizer conversion factors.** In the case that specific values to convert tonnes of fertilizer product used into nutrient concentration are not available, a fertilizer converter tool is provided in the webpage of the International Fertilizer Association.

**Good management measures** to improve fertilizer management and use efficiency include:

- Follow protocols as per extension service or retail outlet recommendations or local regulations, not exceeding recommended doses;
- Use soil sampling to perform nutrient budget calculations;
- Perform site-specific nutrient management or precision farming (where possible);
• Use an organic source of nutrients (including manure or composting residues) alone, or in combination with synthetic or mineral fertilizers;
• Use legumes as a cover crop or intercrop to reduce fertilizer inputs; and
• Consider soil type and climate in deciding fertilizer application doses and frequencies.

6. FOREST, WETLAND AND GRASSLAND CONVERTED FOR COTTON OR COFFEE PRODUCTION

This indicator measures the conversion of any natural land (e.g., forest, wetland, grassland) to land used for cotton or coffee production. The term forests refers to both primary and naturally regenerating forests. Most of the forest loss takes place in tropical forests which host at least two thirds of the terrestrial species. Stopping deforestation contributes to reducing impacts of climate change as forests absorb carbon dioxide from the atmosphere and store it as biomass.

15.1 Forest area as a proportion of total land area

**DEFINITIONS**

Forest. forest is a land spanning more than 0.5 hectares with trees higher than 5 meters and a canopy cover of more than 10 percent, or trees able to reach these thresholds in situ. It does not include land that is predominantly under agricultural or urban land use.

Naturally regenerating forest: forest predominantly composed of trees established through natural regeneration.

Primary forest: Naturally regenerated forest of native tree species, where there are no clearly visible indications of human activities and the ecological processes are not significantly disturbed.

**METHODOLOGICAL NOTES**

Geo-referenced risk maps. The Global Coffee Data Standard suggests overlaying GPS coordinates of farms with regional deforestation maps to understand areas at risk. Note though that usually only a single GPS point will exist for many smallholder farms, meaning that there often isn’t sufficient
information to track the contribution of individual farms to deforestation in most cases. However, even with single GPS points, general farming areas prone to deforestation will still be visible.

7. **Greenhouse Gas Emissions**

This indicator is defined as the ratio between CO2 equivalent emissions from agricultural activities and the marketable biomass produced: cotton lint or Green Coffee Beans (GBE). The scope of the indicators include direct and indirect emissions (1.2 and 3) including all emissions occurring upstream and at the farm from cotton production and until the ginning process. Soil carbon sequestration is not included at this stage.

<table>

Farmers’ interviews and secondary data

**SDG reference**
13.2.2 Total greenhouse gas emissions per year

Similar to the pesticide risk indicator, several tools have been developed to quantify on-farm greenhouse gas emissions. A user-friendly option for cotton and coffee is the Cool Farm Tool. The tool is suitable for farm-level estimates and flexible in the definition of the assessment boundaries. A complementary tool is the geoFootprint which is developed to map and visualize crop carbon footprints at a larger scale (coffee is not included at this stage). A comparison of the scope of the two tools is reported in the table below.
## Cool Farm Tool vs GeoFootprint

<table>
<thead>
<tr>
<th>Scope</th>
<th>Cool Farm Tool</th>
<th>GeoFootprint</th>
</tr>
</thead>
<tbody>
<tr>
<td>User-defined system boundaries, i.e. GHG footprint is calculated for the elements recorded by the end user and only those</td>
<td>Scope 3 at the farm exit gate (i.e. including all emissions occurring upstream and at the farm). Default data are provided</td>
<td></td>
</tr>
<tr>
<td>Farm level (even plot level), without default data. All must be recorded by the end-user</td>
<td>Default data are provided for every parameter at maximum granularity of 10x10 km. All defaults except soil characteristics can be overwritten to recalculate customized emission factors</td>
<td></td>
</tr>
<tr>
<td>Focus on GHG emissions. Includes calculation for water footprint and biodiversity indicators (in progress)</td>
<td>Multiple indicators: climate change (GHG emissions), water withdrawal, water scarcity, eutrophication potential, acidification potential, biodiversity loss, ecosystems quality, soil organic carbon change, soil erosion</td>
<td></td>
</tr>
</tbody>
</table>

8. **YIELD (AVERAGE)**

High land productivity (yield) is likely to lead to better economic returns and to reduce pressure on increasingly scarce land resources, commonly linked to deforestation and associated losses of ecosystem services and biodiversity.

<table>

               - Conversation factors to lint and to GBE |
| Data collection | Yearly |
| Reporting | 3-year average |
| Data sources | Farm cash records, farmer interviews |
| SDG reference | SDG 2.4.1. Percentage of agricultural area under productive and sustainable agriculture |

**METHODOLOGICAL NOTES**

**Conversion factors**

*Seed cotton conversion to cotton lint.* This indicator requires conversion from seed cotton to cotton lint in countries where yield is measured in kg of seed cotton, which includes the weights of both the seeds and the lint. ICAC publishes ginning percentages for 37 cotton producing countries which can be used to convert seed cotton production to lint. In case of multiple pickings, the average yield is calculated.

*Coffee amount harvested.* Coffee amount harvested requires local unit conversion to kgs. The main coffee forms considered are Dried Cherry, Parchment and FAQ (cleaned/re-processed). Amount sold can be a suitable proxy where harvested amounts are unknown (i.e., many smallholders will only know production volumes when their product is weighed at the mill).

**REFERENCES**

- ICAC Cotton Data Book, 2020
9. **Net average returns from cotton and coffee production (Living income in future)**

This indicator tracks the crop profitability as an important dimension of its economic sustainability. The indicator calculates the average gross income from seed cotton or coffee minus the cost of production. The indicator therefore measures the net operating income generated by cotton or coffee, as distinct from the total income of the farming household, which can also include remittances and off-farm income.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Economic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area</td>
<td>Economic viability</td>
</tr>
<tr>

<tr>
<td>Target</td>
<td>Increasing returns over time</td>
</tr>
</tbody>
</table>
| Data points |  • Cost of cultivation (inputs and operational costs)  

  • Gross income (from the selling of the crops and by-products marketed) on seed cotton and GBE  

  • Cotton harvested area or Coffee productive land in ha  

  • Currency conversions rates to USD |
| Data collection | Yearly |
| Reporting | 3-year average |
| Data sources | Farm cash records, farmer interviews |
| SDG reference | |

**Definitions**

**Cost of cultivation.** Cost of cultivation includes all input costs and manpower/operational costs associated with the inputs. It however does not include ginning cost, land rent, taxes, etc.

**Operational costs.** The operation costs include:

  • Machinery, tools needed to apply the inputs
  
  • Electricity/diesel
  
  • Transportation
  
  • Labour
  
  • Consultants cost (wherever applicable)

**Gross income.** Gross Income is the income generated through the selling of seed cotton (includes lint and seeds) or GBE.

**Net average returns.** Net average returns on seed-cotton or coffee per ha are calculated as gross income on seed cotton or GBE minus the total cost of cultivation.
METHODODOLOGICAL NOTES

The computation of net returns requires basic financial transactions which are usually maintained in large commercial farms, but not often in small scale farming. If farm records are not available, returns can be estimated based on farmer declaration of outputs and inputs quantity and value.

Currency conversation into USD: the International Monetary Fund (IMF) provides official exchange rates on a monthly basis:
10. **PRICE (AT FARMGATE)**

This indicator refers to the average price received per tonne of seed cotton or coffee (GBE).

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Economic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area</td>
<td>Economic viability</td>
</tr>
<tr>
<td>Unit</td>
<td>Local currency per tonne of seed cotton or coffee (GBE)</td>
</tr>
<tr>
<td>Relevance</td>
<td>All farms. Relevant to premium-based standards only.</td>
</tr>
</tbody>
</table>

**METHODODOLOGICAL NOTES**

**Multiple sales.** For multiple sales, calculate the average price of sales. The average price can then be compared to the global reference price (e.g. ICAC, ICO). This approach avoids the additional time and resources necessary for detailed accounting and asking about each sale (and the associated premiums, deductions or bonuses) while still providing good results.

For countries like USA, BRAZIL, AUSTRALIA values will be provided for lint and cotton seed and converted into seed cotton.
11. PROPORTION OF WORKERS EARNING A LEGAL MINIMUM WAGE BY GENDER

This indicator allows identifying farms that do not pay a fair remuneration to all employees. The wages paid are an indication of the economic risk faced by unskilled workers in terms of remuneration received, the later benchmarked against the minimum wage set at national level in the agricultural sector. All living wages or wages of all workers and employees should be equal or above existing official national minimum wages or sector agreements, whichever is higher.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Social</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area</td>
<td>Labour rights</td>
</tr>
<tr>
<td>Unit</td>
<td>Daily average earnings for farm labour compared to (rural) minimum wage in local currency and also expressed as a percentage of the rural minimum wage (where that exists), alternately to the national minimum wage.</td>
</tr>
<tr>
<td>Relevance</td>
<td>Farms that employ hired labour; not applicable to farms that employ only family labour</td>
</tr>
<tr>
<td>Target</td>
<td>100% - Entry criterion for sustainability standards</td>
</tr>
</tbody>
</table>

**Data points**
- Total labour cost in the last 12 months/season
- # hired (permanent and temporary) workers working on the farm in the last 12 months/season
- Total labour cost in the last 12 months/season
- Average daily wage rate paid to each worker
- National minimum wages
- Currency conversion rates

**Data collection**
Yearly

**Reporting**
Yearly

**Data sources**
Work contracts, farmer interviews

**SDG reference**
8.5.1 Average hourly earnings of female and male employees, by occupation, age and persons with disabilities

**Definitions**

**Agricultural skilled workers.** Skilled agricultural workers grow and harvest field or tree and shrub crops; in order to provide food, shelter and income for themselves and their households. A full description of tasks performed by agricultural skilled workers is provided in the Sub-major Group 61 Market-oriented Skilled Agricultural Workers of the International Standard Classification of Occupation (ISCO) classification.

**Wages.** Compensation includes both monetary and in-kind payment.

*Definitions adapted from Fairtrade Standard for Small-scale Producer Organizations:*
Workers. In the context of the Delta framework, workers are all workers including migrant, temporary, seasonal, sub-contracted and permanent workers. Workers are waged employees hired to work in the field.

Migrant worker. A migrant worker is a person who moves from one area within her or his own country or across the borders to another country for employment. A migrant worker works for a limited period of time in the region that he/she has migrated to. Workers are not considered migrant after living one year or more in the region where they work, and if either a permanent position has been granted by the employer or legal permanent resident status has been granted.

Seasonal worker. Seasonal worker refers to a worker whose work by its character is dependent on seasonal conditions and is performed only during part of the year.

Temporary worker. A temporary worker is a person who works at the company on a non-regular, short term basis. A temporary worker may be a seasonal worker.

12. INCIDENCE OF THE WORST FORMS OF CHILD LABOUR

This indicator tracks the employment of children below the age of 15 or under the age defined by local law, whichever is higher. Child labour is “work that deprives children of their childhood, their potential and their dignity, and that is harmful to physical and mental development”. Not all work carried out by children is considered child labour. Some agricultural tasks may help children acquire important livelihood skills and contribute to their survival and food security. However, many child labourers in agriculture are trapped in hazardous work. Child labour in cotton and coffee production has been reported in several countries, primarily as a consequence of the low farm income.

Assessing child labour in the field remains complex and sensitive. Opportunities for collaboration with UN dedicated agencies such as FAO and ILO are a real opportunity which should be explored in many countries.

### Definitions

**Child labour.** Child labour is defined by ILO as work that impairs children’s well-being or hinders their education, development and future livelihoods. The Convention on the Rights of the Child (UN, 1989) recognizes and emphasizes the child’s right to education and the right of the child to be protected from economic exploitation and from performing any work that is likely to be hazardous, interfere...
with the child’s education, or be harmful to the child’s health or physical, mental, spiritual, moral or social development.

The international regulations and Conventions dealing with child labour refer to the following distinctions/concepts:

- Working children
- Child labour
- Age-appropriate tasks
- Light work
- Worst forms of child labour
- Hazardous work

**Minimum age.** The ILO Minimum Age Convention, 1973 (No. 138) specifies the minimum age for different types of employment:

- 13 years for light work
- 15 years for ordinary work
- 18 years for hazardous work

Developing countries that ratified Convention No. 138 have the option to designate a higher age or, in exceptional cases, an age 1 year lower than the standard (e.g. 14 years for ordinary work).

- Age-appropriate tasks become “child labour” when children:
  - Are too young for the work they are undertaking;
  - Work too many hours for their age;
  - Undertake work of a hazardous nature or in hazardous conditions;
  - Work under slave-like conditions; or
  - Are obliged to undertake illicit activities.

**Hazardous work.** Hazardous work in the context of crop production includes exposure to sharp tools and dangerous machinery, injuries from animals, exposure to extreme environmental conditions, exposure to agrochemicals, long working hours in fields (especially in extreme weather conditions); and physically strenuous or repetitive activities. Hazardous work is an example of the worst forms of child labour (ILO Convention, 1999 (No. 182). For all full description of the definitions refer to the FAO Handbook.

**Family labour:** Children below 15 years of age only work after school or during holidays, the work they do is appropriate for their age and physical condition, they do not work long hours and/or under dangerous or exploitative conditions and their parents or guardians supervise and guide them.

**METHODOLOGICAL NOTES**

Monitoring child labour is a complex issue. The FAO Handbook for monitoring and evaluation of child labour in agriculture includes a toolkit designed to assess and gather data on child labour in family-based agriculture. It is recommended to use a combination of different tools during data collection, in order to obtain diverse data which can be cross-checked against each other. With a combination of
tools, the strengths of one can overcome the potential weaknesses of another, and the data obtained are therefore more reliable. Standard setting initiatives can monitor the incidence of child labour based on audits and additional qualitative assessments.

**REPORTING**

- Reduction in percentage of children under the legal working age
- Reduction in percentage of children engaged in hazardous work

**REFERENCES**

13. **INCIDENCE OF FORCED LABOUR**

This indicator tracks the systematic or individual use of forced labour in cotton and coffee production.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Social</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area</td>
<td>Forced Labour</td>
</tr>
<tr>
<td>Unit</td>
<td>Number of people, over 17 years of age, engaged in forced labour, by sex and age.</td>
</tr>
<tr>
<td>Relevance</td>
<td>Countries with reported incidence of forced labour</td>
</tr>
<tr>
<td>Target</td>
<td>0%. Exclusion criterion for sustainability standards.</td>
</tr>
</tbody>
</table>

**DEFINITIONS**

**Forced labour.** Forced labour as all work or service: - which is not voluntary; and - which is exacted under the menace of a penalty. A person is classified as being in forced labour if engaged during a specified reference period in any work that is both under the threat of menace of a penalty and involuntary.

**Work:** Work is any activity performed by persons of any sex and age to produce goods or to provide services for use by other or for own use.

**Involuntary work:** Involuntary work is any work taking place without the free and informed consent of the worker.

**Threat or menace of any penalty:** Threat or menace of any penalty is any means of coercion used to impose work on a worker against his or her will.

**Reference period.** The reference period can be short such as last week, last month or last season, or long such as past year, past five years or lifetime.

*ILO Forced Labour Convention, 1930 (No. 29)*

**METHODOLOGY**

Standard setting initiatives can monitor the incidence of forced labour based on audits and additional qualitative assessments. Further research is needed to develop a more comprehensive methodology.

14. WOMEN EMPOWERMENT

The Abbreviated Women’s Empowerment in Agriculture Index (A-WEAI) developed by IFPRI is a survey-based index for measuring empowerment, agency, and inclusion of women in the agriculture sector. It consists of six composite indicators, with weights for each indicator adjusted accordingly. The A-WEAI includes a simplified 24-hour recall time module that collects information only on primary activities, and streamlined sections on production decisions and resources.

<table>

| Data collection | Yearly |
| Reporting       | Yearly |
| Data sources    | Farmers/ household interviews |
| SDG reference   | 5.5 Ensure women’s full and effective participation and equal opportunities for leadership at all levels of decision-making in political, economic and public life |

DEFINITIONS

The A-WEAI has 6 sub-indicators mapped to three domains: intrinsic agency (power within), instrumental agency (power to), and collective agency (power with). A gender parity index compares the empowerment scores of men and women in the same household.

**Input in productive decisions**: What decisions are you a part of? What is your role in making these decisions?

**Income**: Do you have input in decisions on how income and output from all ag activities you participate in is spent or used? Do you have input in decisions on how income from non-agricultural activities is spent?

---

6 [https://www.ifpri.org/project/weai](https://www.ifpri.org/project/weai)
Credit: do you contribute to household decisions on credit (e.g. taking out a loan)? Can you get a loan if you wanted to? Do you have access to a financial account?

Work balance: how many hours a day do you work? How much of that time is spent on care giving for children?

Group membership: are you a member of a group in your community?

METHODODOLOGY

The A-WAEI comes with a detailed score-based methodology to compute the index available at: http://weai.ifpri.info/versions/a-weai/
15. **NUMBER OF FATALITIES AND NON-FATALITIES ON THE FARM BY GENDER**

This indicator tracks the number of fatalities and non-fatalities occurring on farm. Worker health and safety refers to the principle that workers should be protected from sickness, disease and injury arising from their employment. In the case of cotton and coffee production, a specific type of non-fatalities that deserve close monitoring are acute and chronic effect of pesticide exposure.

### Definitions

**Occupational injury** is defined as any personal injury, disease or death resulting from an occupational accident. An occupational injury is different from an occupational disease, which comes as a result of an exposure over a period of time to risk factors linked to the work activity. Diseases are included only in cases where the disease arose as a direct result of an accident.

The ILO’s Safety and Health in Agriculture Convention, 2001 regulates specific risks to workers in the agricultural sector, relating for example to machinery safety and ergonomics, handling and transport of materials, sound management of chemicals, animal handling, protection against biological risks, and welfare and accommodation facilities. *ILO Convention 155 on Occupational Safety and Health*

### Methodology

The Fatal OR non-fatal occupational injury rate can be calculated separately using the following formula:

\[ \text{Fatal OR non-fatal occupational injury rate} = \frac{\text{Number of fatal OR non-fatal occupational injuries in the reference group}}{\text{Number of farmers and workers in the reference group}} \times 100 \]
Occupational injuries are often underreported, which means that occupational injuries statistics from administrative records or registry systems may be less than comprehensive.

A self-monitoring methodology for acute pesticide poisoning among farmers has been developed by the FAO, which can be adapted to other farming situations.
